RQ: Do citizens respond politically to local economic conditions?

- Conflicting findings in existing literature

»(...) the local economy **has an impact** on presidential election outcomes (...)« (Lenz & Healy, forthcoming)

»(...) local economic conditions related to the housing market **do not appear to play an important role** in U.S. election results (...)« (Hall et al., 2017)

- Our argument: conditional on *contextual priming* from local econ activity
- → citizens more responsive when local econ activity is salient
- focus on housing market (empirically important, high-quality local data)

» *H1 (Local economic conditions hypothesis)*: When local house prices rise, individuals are more likely to support the incumbent government.«

» *H2 (Contextual priming hypothesis)*: The association between changes in local house prices and support for the incumbent government is stronger when individuals are more exposed to local housing market activity.«

Denmark ca. 2002 - 2015.

- ① experienced very volatile housing bubble
- ② detailed data from the public registries on local housing markets
- ③ link the housing market data to voting behavior in two different data sets:
  - precinct-level election returns
  - two-wave panel survey of reported voting

Trends in real house prices. Source: The International House Price Database.

DV is support for gov't parties at precincts across elections in '05, '07, '11, '15.

↪ smallest unit at which election outcomes are observed (3,000 voters on average)

IV is year-over-year changes in the price of real-estate sold in the precinct's zip code.

↪ Data from the Danish Mortgage Federation.

We link precincts to zip-codes by identifying the zip code of the precinct's polling place.

↪ we also have information on unemployment and median income in each zip-code.

$$\text{govt}_{it} = \Delta \text{price}_{it} + \epsilon_{it} + \gamma_t + \epsilon_{it} + \pi_i + \epsilon_{it} \\ + \text{econ}\beta + \epsilon_{it}$$

$$\text{govt}_{it-1} = \Delta \text{price}_{it} + \gamma_t + \pi_i + \text{econ}\beta + \epsilon_{it}$$

Use a two-wave panel survey of Danish citizens; interviewed in the aughts, '11.  
~> Link these respondents to the national registers.

Why use this data as well?

- Replication (/methodological triangulation).
- Explore individual level moderators to get at mechanism.
- Allows us to define context in flexible ways (cf. MAUP).

Larsen et al.

Conditional Impact

DV is reported vote choice for gov't party.

IV is changes in the price of real-estate sold in residential context (dif interpretations).

We use a linear regr with fixed effects to estimate the effect of local housing prices.

↪ Controls: Unemployment, Income (personal, context)

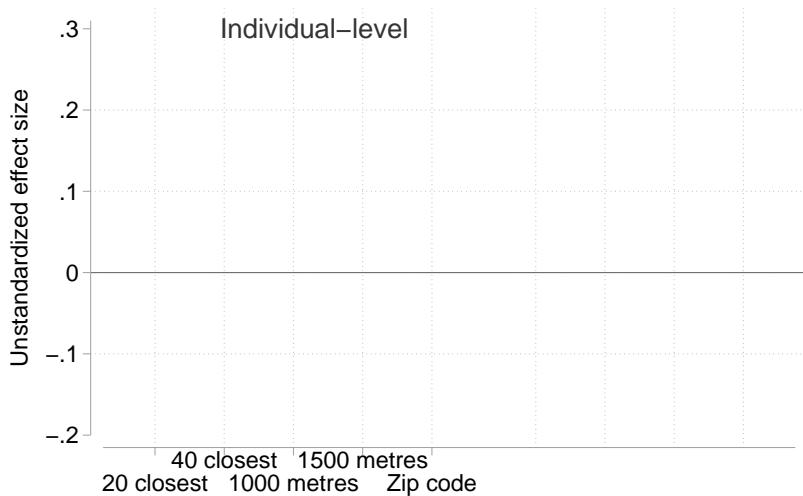

↪ Use an LPM as a link function.

Precinct-level data

Precinct-level data

We find that local housing prices do drive incumbent support.  
~> especially for those who engage with the local housing market.

Suggests that local economy matters.

- People make inferences about pol's based on how local community is doing.
- Means that pol's need to worry about 'geography of grievances'.

Also suggests that, more broadly, housing markets matter politically.  
~> voters adapt, focus on new parts of the economy.
